

Orbital Alert API Test Summary

Documentation of API Testing Steps and Results (May 28, 2026)

1. Create Region

The 'POST /api/regions' endpoint was used to create a new region. The example sent included the name 'Santos - Zona Portuária', city 'Santos', state 'SP', latitude -23.9608, longitude -46.3336, satelliteRiskScore 85, and riskLevel 'HIGH'. It returned an object containing an id and the submitted fields, confirming successful creation.

2. View Region

After creation, 'GET /api/regions/{id}' returned the details of the region with id 2, matching the values submitted.

3. Create Sensor

The 'POST /api/sensors' endpoint added a sensor to the region by specifying the regionId, type (e.g., WATER_LEVEL), status ACTIVE, and unit '%'. The response contained the sensor id and associated region id.

4. View Sensor

'GET /api/sensors/{id}' returned the sensor's details, confirming that the sensor had been correctly associated with the region.

5. Create Reading

Using 'POST /api/readings', a reading with sensorId 1 and value 87.5 was recorded. The response included the reading id, sensorId, sensorType, value and measuredAt timestamp.

6. View Alerts

'GET /api/alerts' returned a list of alerts. For a high water level reading, two alerts were generated with severity 'HIGH', status 'OPEN', and description 'Nível de água acima do limite.'.

7. Resolve Alert

'PUT /api/alerts/{id}/resolve' updated an alert with status OPEN to RESOLVED. The response returned the resolved alert with the resolvedAt timestamp.

8. List Active Alerts

'GET /api/alerts/active' listed only those alerts still open. After resolving the first alert, only the second remained in the active list.
